<sup>c</sup>*The Feuerstein Institute –The International Institute for the Enhancement of Learning Potential, Jerusalem, Israel*

**Abstract.** NG is an architect who suffered a left occipital-parietal hemorrhage cerebral vascular accident (CVA) in 2000, resulting in aphasia of Wernicke and conduction types. He was characterized with fluent paraphasic speech, decreased repetition, and impaired object naming. Comprehension was relatively preserved but reading and writing were severely compromised, as well as his auditory working memory. Despite a grim prognosis he underwent intensive aphasia therapy, lasting from 2001 to 2010, at the Center for Cognitive Rehabilitation of the Brain Injured at the Feuerstein Institute. The tailored-made interventions, applied in NG's therapy, were based upon the implementation of the principles of the Structural Mediated Learning Experience (MLE) and the Feuerstein Instrumental Enrichment (FIE) Program, to optimize his rehabilitation. As a result NG improved in most of his impaired linguistic capacities, attested by the results of neuropsychological and linguistic assessments performed throughout the years. More importantly, he was able to manage again his daily functions at a high level, and to resume his occupational role as an architect, a role which he holds to this day.

**Keywords:** Aphasia, rehabilitation, structural cognitive modifiability, mediated learning experience

### 1. Introduction

Aphasia is an acquired language impairment that affects comprehension and production of verbal

language and is incurred by acquired brain damage, usually focused in the left cerebral hemisphere (Damasio & Damasio, 2000). The language deficits in aphasia may be multi-faceted and encompass different aspects of language, such as phonology (speech sounds), grammar (word order and word endings), lexicon (word finding) and semantics (word meanings). Other impairments such as alexia and agraphia also co-occur with aphasia, as they all depend on

35 the same symbolic language mechanism used in ver- 87  
36 bal language (Hillis, 2007; Tippett, Niparko & Hillis, 88  
37 2014). 89

38 Due to the complexity of the language apparatus, 90  
39 aphasia may be manifested in different forms. Several 91  
40 classification methods were proposed over the years 92  
41 (Benson & Ardila, 1996), but they all share the basic 93  
42 patterns that were described originally by Wernicke 94  
43 and Lichtheim in the 19th century. According to their 95  
44 typology aphasia can be classified into *non-fluent* and 96  
45 *fluent* aphasias: Anatomically, non-fluent aphasias 97  
46 occur as a result of lesions affecting left pre-rolandic 98  
47 regions, while fluent aphasias arise as a consequence 99  
48 of damage to left post-rolandic regions. Non-fluent, or 100  
49 Broca's, aphasia is characterized by deficits in spon- 101  
50 taneous speech and sentence repetition (reduction in 102  
51 phrase length, diminished words per minutes). Audi- 103  
52 tory comprehension is relatively spared, although 104  
53 these individuals encounter difficulties with complex 105  
54 sentences (e.g., sentences with object relative clauses 106  
55 "the girl that the boy kissed ran way", Hillis, 2007). 107  
56 Broca's aphasia is associated with large left frontal- 108  
57 subcortical lesions. Other types of non-fluent aphasia 109  
58 include transcortical motor aphasia, global aphasia 110  
59 and mixed transcortical aphasia. 111

60 In fluent, or Wernicke's aphasia, verbal expression 112  
61 is characterized by relatively intact, yet meaningless 113  
62 spontaneous speech and repetitions, with relatively 114  
63 poor comprehension of words, sentences, and conver- 115  
64 sation. Wernicke's aphasia is associated with lesions 116  
65 affecting the posterior portion of the left superior tem- 117  
66 poral gyrus. Three other variants of fluent aphasia are 118  
67 transcortical sensory aphasia, conduction aphasia and 119  
68 anomic aphasia. In the latter two types, auditory asyn- 120  
69 tactic comprehension is intact while confrontation 121  
70 naming is severed. Repetition, which is impaired in 122  
71 conduction, but not in anomic aphasia, distinguishes 123  
72 between the two. 124

73 Recovery from aphasia varies widely between indi- 125  
74 viduals, their aphasia types and its initial severity 126  
75 (Koenig-Bruhin et al., 2013). Some restoration of lan- 127  
76 guage functions following stroke typically occurs in 128  
77 the acute phase of recovery (DiFrancesco, 2013). In 129  
78 fact, speech features normalize in about one-third of 130  
79 patients after one month (Laska et al., 2011). How- 131  
80 ever, severe chronic aphasia is not rare, and 19% of 132  
81 stroke patients still suffer from persistent communi- 133  
82 cation disorders a year on (Dijkerman et al., 1996). 134

83 There is no universally established intervention 135  
84 that is valid for all aphasia patients, but usually the 136  
85 therapist will choose from a variety of therapeutic 137  
86 methods and apply an individually adapted program 138

of treatment (Brady et al., 2012). Clinicians agree that  
intensive speech therapy is helpful for most aphasic  
patients (Barisa, Noggle, Salisbury & Boseck., 2013).  
Regarding the acute phase, two classes of treatment  
can be identified, cognitive or functional: Cognitive,  
or neuro-linguistic oriented, treatments concentrate  
on language-specific impairments, with treatments  
focusing on specific tasks such as naming, semantic  
or phonological training, sentence production, writ-  
ing or reading (Koenig-Bruhin, et al., 2013). Using  
this approach, rehabilitation efforts are tailored to  
the patient's identified deficits. Although this tradi-  
tional school of thought improves language skills,  
it has been criticized for not improving functional  
communication, the ability to successfully communi-  
cate a message via spoken, written and/or non-verbal  
modalities (Brady et al., 2012). Functional thera-  
pies, therefore, utilize compensatory strategies that  
rely on the individual's strengths, with the aim of  
enhancing their social participation and their quality  
of life (Schwartz & Fink, 2003). These strategies may  
include writing, use of symbolic gestures and facial  
expressions.

In treating patients with chronic aphasia, which  
continues beyond six months post stroke onset,  
interventions are individually tailored and are  
used in conjunction with additional group therapy  
(Cherney et al., 2008; Cicerone et al., 2011), or  
involvement of partners in community-based aphasia  
programs (Allen, et al., 2012). Several methods  
were established as effective in treating chronic  
aphasia. For example, in linguistic task-specific  
therapy, treatment-specific effects are linked to  
the type of impairment (Teasell et al., 2009). In  
constraint-induced aphasia therapy (CIAT), the  
use of non-verbal communication strategies is not  
allowed. This type of therapy may result in improved  
language function and everyday communication  
(Cherney et al., 2008; Cicerone et al., 2011).

Since speech therapy is most effective when pro-  
vided intensively, it must be a mutual endeavor  
involving the aphasic participants, their families,  
and the speech therapists (Basso & Macis, 2011).  
This active continual collaboration will maximize  
functional communication (Brady et al., 2012). An  
example of this is family members and carers being  
trained to assist with additional self-managed com-  
puter treatment (Teasell et al., 2009; Basso & Macis,  
2011). Another aspect of the treatment intervention,  
related to the exposure to FIE, is the role of face-to-  
face direct interactions in relation to (and supported  
by) using the computer for elaboration and practice.

In the current study we present the case of NG, who underwent an intensive rehabilitative treatment of his aphasia following a cerebral vascular accident (CVA), which he experienced at the age of 53. Between the years 2001–2010 NG attended the Center for Cognitive Rehabilitation of the Brain Injured (CCRBI) at the Feuerstein Institute (FI) where he received therapy, based on the principles of the *Structural Cognitive Modifiability* (SCM) and *Mediated Learning Experience* theories (MLE; Feuerstein, Rand, Hoffman, & Miller, 1980; Feuerstein, Feuerstein, Falik & Rand, 2002). The SCM theory is based on the view that an individual has a natural propensity to change, and to adapt to his environment through structural cognitive changes. The MLE theory posits that the structural cognitive modifiability is realized through a mediating agent (e.g., parent, teacher), who serves as an intermediate between the environment and the learner. Through selection, enhancement, and organization of the relevant stimuli for the learner, the mediating agent helps to maximize the functioning of the learner. Moreover, enhancing cognitive modifiability through mediated learning allows the individual to learn additional and even more complex cognitive operations and strategies than those formally taught (LeBeer, submitted).

One of the main vehicles used to achieve cognitive modifiability is through a cognitive enrichment program called *Feuerstein Instrumental Enrichment* (FIE, Feuerstein et al., 1980). The FIE program is designed to enhance the capacity of the individual to become modified as a result of mediation, using a variety of instruments. It includes 15 paper and pencil instruments, each consisting of a set of problems with increasing levels of difficulty. For each instrument, a set of teaching procedures is suggested, including, as a major component, suggestions how to generalize acquired principles to domains and contexts that are beyond the original domains presented.

Since 1996, over 120 patients, suffering from either traumatic (concussions, contusion, diffuse axonal injuries, penetrations) or acquired brain injuries (CVAs, anoxias) have been treated at the CCRBI. Most of them were suffering from multiple, mostly severe, symptoms, which include, among others, executive function deficits, memory loss, aphasia, neglect and hemiparesis. Although they received rehabilitation at hospital prior to their arrival, their severe condition required an additional rehabilitative process, focusing on the cognitive rehabilitation potential that is presumed to be available to these injured individuals. Patients were assessed upon

entry, and an intensive treatment program was built for them according to their level of functioning and propensity to change. Intensity is defined as duration of treatment (over a multi-year period), and number of sessions per week (usually involving 4–6 hours). The intensity factor is deemed essential to the success of the intervention, and the eventual recovery of functions in the patient. In addition to the FIE component, the treatment program may include speech therapy, occupational therapy, reading and writing or computer skills, with FIE, imbuing all of these therapies.

In addition to the treatment NG received at the CCRBI he was assessed at several time periods following his CVA, the latest in 2014. Thus, the present case study presents a description of an extensive cognitive therapy, directed toward his aphasia and other aspects of deficient functioning, and a long-term follow-up assessment of the consequences of this therapy.

## 2. Method

### 2.1. General background information

NG is now a 68 year old male, born in an English-speaking country but currently living in a central city in Israel. He is married with three children. He is right-handed, and had no known developmental problems or learning difficulties when he was younger. He studied architecture in leading universities abroad and has an MA in both architecture and civil engineering.

NG and his family moved to Israel in the late 1970's where he started his own architectural practice, specializing in restoration and designing old houses. Prior to his CVA he was managing a medium size office and employing several architects. He was (and to some degree still is) very prominent in his field and worked on many prestigious projects. Prior to this, NG had hypertension (treated by homeopathic medication) and borderline diabetes (treated by a diet).

### 2.2. Incident and Neurological Background

NG suffered a left hemorrhagic CVA in the spring of 2000. He was hospitalized due to dizziness, headache, nausea, vomiting and speech disturbances. On neurological examination he was conscious, but had comprehension difficulties, executed commands only partially, his speech was unclear and included paraphasias, and he had mainly sensory dysphasia

237 and anomia. A CT scan showed a left occipital-  
238 parietal hemorrhage, mild edema surrounding the  
239 hemorrhage and mild shifting of the mid-line. There  
240 was also the impression of his right hand and leg drop-  
241 ping but towards the end of his hospitalization there  
242 was a clear improvement in his speech difficulties and  
243 in the weakness on his right side.

244 After two weeks NG was transferred to the reha-  
245 bilitation unit in the hospital. On the day of his  
246 transfer his functional independence measure (FIM)  
247 score was 92/123. During his stay he received multi-  
248 disciplinary rehabilitation therapy with emphasis on  
249 his severe apraxia, damaged visuo-motor organiza-  
250 tion, neglect to the right visual field and decreased  
251 understanding of numbers. According to a speech  
252 therapist report at the beginning of the treatment  
253 language comprehension was severely impaired.  
254 Bucofacial apraxia, anomia, alexia and agraphia  
255 (with the preservation of automatic writing) were  
256 also present. He spoke mainly Hebrew and gradu-  
257 ally started speaking English, his native language.  
258 An audiometric examination showed a moderate to  
259 severe sensory hearing deficit in his right ear. An MRI  
260 in the summer of 2000, with and without contrast,  
261 showed a hematoma involving the left occipital and  
262 posterior aspect of the parietal lobe with a surround-  
263 ing hemosiderin ring.

264 A neurological report concluded that NG had left  
265 brain dysfunction involving the posterior perisylvian  
266 region and at least more anterior involvement that  
267 may account for the transient motor difficulties and  
268 the conduction difficulties. There was also posterior  
269 extension involving parietal or occipital visual path-  
270 ways. He was described as having both Wernicke's  
271 aphasia and conduction aphasia qualities. NG was  
272 discharged from the hospital in the autumn of 2000.  
273 His FIM score upon his discharge score had increased  
274 to 121/126. An MRI with Gadolinium (and compu-  
275 tation of T1 and T2 before and after the injection of  
276 Gadolinium) showed a hemorrhage in an absorption  
277 phase in the left occipito-parietal area with the focus  
278 extending to the left lateral ventricle. There was still  
279 an area of increased signal in the T1 series in the  
280 center (E/12) with no evidence of relaxation after the  
281 Gadolinium.

### 282 2.3. Rehabilitation process: 283 Intervention/Treatment

284 As part of his rehabilitation process, NG attended  
285 the CCRBI at the FI, receiving therapy intermittently  
286 between 2001 and 2010. However, the most intensive

287 years of rehabilitation occurred between 2001 and  
288 2003. The therapy he received at the FI included the  
289 FIE program, speech therapy, occupational therapy,  
290 computer instruction and reading/writing instruc-  
291 tions. His treatment implemented the institute's  
292 therapeutic principles, infusing the parameters of  
293 MLE (Feuerstein, et al., 2006) into all aspects of the  
294 interventions.

295 Specifically, between 2001 and mid-2003, NG  
296 received therapy (conducted in English) 15 hours  
297 a week (4-5 times a week), of which speech and  
298 language therapy took up 4-5 hours weekly, with  
299 his cognitive functions mediated developmentally  
300 according to a linguistically-oriented responsive  
301 environment infused with processes of strategic  
302 thinking. This intensive program was reduced from  
303 mid-2003 to 2-3 times a week. The most detailed  
304 information on hours of treatment provided were  
305 between August 2003 and September 2004, where  
306 he received a total of nearly 200 hours of therapy.  
307 During that particular year, he received 67 hours of  
308 speech therapy, 53 hours of computer instructions and  
309 79 hours of reading and writing instructions.

310 Before starting his rehabilitation at the CCRBI,  
311 NG's spontaneous speech was fluent with some  
312 agrammatism, semantic and literal paraphasias and  
313 preserved prosody and articulation. Repetition skills  
314 and word retrieval were severely impaired. Com-  
315 prehension of spoken language was variable with  
316 the patient demonstrating difficulties executing com-  
317 mands that included prepositions. Reading was  
318 severely impaired as NG was unable to read aloud.  
319 However, he was able to derive meaning from writ-  
320 ten language to a certain extent, especially in silent  
321 reading. Writing was also severely impaired.

322 Speech therapy was conducted in English and  
323 focused, among other things, on auditory acoustic  
324 analysis, mechanical aspects of articulation, auditory  
325 feedback, repetition, awareness of errors, decreasing  
326 perseverations, and increasing phonological and mor-  
327 phological awareness. NG's speech therapists also  
328 focused on his word retrieval skills, retaining and  
329 recalling critical personal and professional informa-  
330 tion, syntax and grammar. Technology, such as text  
331 to audio software, was also used to aid him in his pro-  
332 fessional life, reading skills and conversation skills. His  
333 reading and writing therapists at the FI also used the  
334 method and workbooks of the Wilson reading system  
335 (Wilson, 2004), alongside their own therapy tech-  
336 niques. The computer instructions that NG received  
337 mainly focused on numerical perception and mathe-  
338 matical skills.

Speech and language therapy reports during this intensive period indicated general progress in language capacities. A speech-therapy report from late 2002 indicated improved speech and word-finding abilities (less paragrammatism and circumlocutions), with relatively intact comprehension, although the speaker's pace of speech has to be slower than normal to allow NG more processing time. Reading aloud of simple sentences was possible provided they followed simple sentence structures. Writing common word from visual representation was also achieved. In addition, NG was beginning to write new words from dictation via phoneme-grapheme conversion. Difficulties in self-monitoring of grammatical errors and understanding of complex speech (jokes, ambiguities) were noted. This report was further corroborated by an additional observation made in the beginning of 2003. It was noted then that NG made progress in his ability to repeat words, associate letters with their sounds in order to orally read a written word, and at times use this same strategy to retrieve a word while in conversation. Conversation skills were also found to be significantly improved. NG successfully was able to discuss different topics using substantive vocabulary to get to his point.

Between 2004 and 2008 NG received further therapy (mostly speech therapy) of approximately 353 hours in total. The therapy focused primarily on word-retrieval, sound-letter association, phonemic awareness, numbers and supplying personal information. Overall, NG received throughout the years over 1200 hours of therapy at the FI.

Throughout NG's rehabilitation, his wife was always included in the therapeutic process. Following advice, she attended every single therapy session for the first year of his rehabilitation. She reported that her presence and support boosted NG's confidence and emotional state. Her involvement continued during his rehabilitation at FI, where his speech therapists would send exercises home for practice and review.

Currently, NG continues to work in his architectural practice, but with reduced hours. His office has downsized and he now works mainly from home. He makes use of a number of different strategies to assist him with his particular difficulties. For example, he uses a program on his iPad called "Speak-it" which reads out emails to him. He also makes lists to assist him with his short-term memory problems. He therefore manages to function on a day-to-day basis at a high level.

## 2.4. Neuropsychological Assessments

NG was assessed several times throughout the years. These assessments were conducted periodically during treatment to assess ongoing treatment effects and to calibrate further interventions. Three language-focused neuropsychological assessments (NA) were conducted: The first (NA1) was administered several months after his CVA, before he commenced his rehabilitation at the FI (December 2000 – January 2001). The second assessment (NA2) was administered two years later, during his rehabilitation period at the FI (February 2003). At the same period NG was also examined in the United States. These assessments are also referred to also as NA2 assessment. The third (NA3) was conducted more than ten years later (June–August 2014) as part of the current research. The first and third assessments were comprehensive, and included, in addition to language, other domains such as learning and memory processes, executive functions and attention.

Testing on all occasions was conducted in English by a native English-speaker, and all test materials were in English. NG cooperated fully with the examiners and invested considerable efforts in the tests. He made eye-contact, behaved adequately, and showed a sense of humor. He performed slowly on many of the tasks and carefully monitored his performance. During the 2014 assessment, NG sometimes expressed disappointment with his performance, particularly in the word retrieval tests. He pointed out his difficulties to the examiner, and as he understands his situation well, it bothered him to do some of the tests.

## 2.5. Tests Administered (in alphabetical order)

### A. Boston Naming Test (BNT; Kaplan, Goodglass, & Weintraub, 1983; NA1, NA2, NA3)

The BNT is a widely used neuropsychological tool that measures word retrieval in individuals with aphasia or other language disturbances. It consists of 60 black and white drawings of items ranging in familiarity such as "house" at the beginning of the test to "sphinx" at its end. The participants have to name the items upon confrontation. If they fail they are given a semantic or phonetic cue.

### B. Cookie Theft Picture (CTP; Goodglass & Kaplan, 1983b; NA1, NA2, NA3)

The CTP description task is part of the Boston Diagnostic Aphasia Examination (BDAAE) and is a measure of discourse production. The picture depicts

438 a household kitchen scene with a boy standing on a  
 439 stool, about to topple over, trying to reach a jar of  
 440 cookies from a cupboard. The sister stands next to  
 441 him and encourages him to take the jar. The mother,  
 442 with her back to the children, is washing dishes in the  
 443 sink and doesn't realize that the water is overflowing.  
 444 NG was asked to look at the picture and describe what  
 445 is happening in it.

446 *C. The Diagnostic Assessments of Reading (DAR;*  
 447 *Roswell, Chall, Curtis & Kearns, 2005, NA2)*

448 This test assesses an individual's relative strengths  
 449 and weaknesses in nine key areas of reading and  
 450 language: Print awareness, phonological awareness,  
 451 letters and sounds, word recognition, word analy-  
 452 sis, oral reading accuracy and fluency, silent reading  
 453 comprehension, spelling and word meaning.

454 *D. Fuld Object Memory Evaluation (FOME,*  
 455 *Fuld, 1980, NA1)*

456 The FOME is a memory assessment measure  
 457 designed to evaluate memory impairments in older  
 458 adults. By using concrete objects it allows the exami-  
 459 nee to encode the information with several sensory  
 460 modalities. The FOME was used in NA1 due to  
 461 NG's naming difficulties and was modified to assess  
 462 his memory, independent of his speech deficits. He  
 463 viewed a group of 10 real objects that were easily  
 464 represented by gestures (e.g. cup – by miming the  
 465 action of drinking). Gestures were assigned to each  
 466 object before they were hidden. In each of 5 trials  
 467 he was asked to recall the 10 objects, either by name  
 468 or by mimicking their use. If unable to recall all the  
 469 objects he was reminded of the remaining ones. In the  
 470 interval between the trials short distractors tasks were  
 471 introduced. In the delayed recall (approx. 5 minutes  
 472 after the completion of the last trial) NG was asked  
 473 to name again the objects. For any items not recalled  
 474 NG was given a 3-item recognition task.

475 *E. Phonological Awareness Test (PAT; Robertson*  
 476 *& Salter, 1997; NA2)*

477 The PAT is a comprehensive assessment of chil-  
 478 dren's phonological awareness, phoneme-grapheme  
 479 correspondences and phonetic decoding skills. Test  
 480 results help educators focus on aspects of a child's  
 481 oral language that may not be systematically targeted  
 482 in classroom reading instruction. The test is geared  
 483 to children aged 5–9 and it includes a wide variety  
 484 of tasks such as rhyming, segmentation, isolation,  
 485 deletion, substitution with manipulatives, blending,  
 486 graphemes, decoding and invented spelling. Perfor-

mance on each of these tasks has been correlated with  
 success in early reading and spelling.

*F. Raven's Colored Progressive Matrices*  
 (RCPM; Raven, 1994, 1995, 1996; NA1, NA3)

The RCPM is a simplified 36-item format of the  
 Raven's Progressive Matrices (RPM) (Raven, 1995).  
 This is a multiple-choice paper-and-pencil test con-  
 sisting of a series of visual pattern matching and  
 analogy problems pictured in nonrepresentational  
 designs. It requires the participant to conceptualize  
 spatial, design, and numerical relationships ranging  
 from the very obvious to concrete to the very complex  
 and abstract. The RCPM consists of sets A and B of  
 the RPM and an intermediate set, Ab, which, like set  
 B, contains both gestalt completion items and some  
 simple analogies.

*G. Rey Auditory Visual Test (RAVLT; Rey, 1964,*  
*NA1, NA3)*

The RAVLT evaluates verbal memory and is com-  
 prised of a list of 15 words that the participant hears  
 and is asked to recall. The list is repeated and recalled  
 5 times and then a second list is introduced and recall  
 is required. After this trial participants are asked  
 to recall again the first list. A delayed-recall and a  
 recognition tasks (the latter consisting of 50 words,  
 including the words from list and distractors) are also  
 administered.

*H. Rey-Osterrieth Complex Figure Test (ROCFT;*  
*Rey, 1941, Osterrieth, 1944; NA1, NA3)*

This test evaluates visuo-spatial constructional  
 abilities, visual memory and executive functions,  
 mediated by the prefrontal lobes. The test consists  
 of a copy task, where the participant is asked to copy  
 a complex figure onto a sheet of paper. Following  
 the copy stage the participant is asked to recall the  
 complex figure either immediately (immediate recall  
 task), on delay (delayed recall task), or both.

*I. Wechsler Adult Intelligence Scale (WAIS;*  
*Wechsler, 1981, 1997; NA1 [WAIS-R], NA3*  
*[WAIS-III])*

The WAIS was administered to assess the general  
 impact of NG's CVA on his general cognitive func-  
 tioning and to track potential changes following the  
 rehabilitation. At NA1 NG was able to perform only  
 a few sub-tests from the general battery due to his  
 severe aphasia (Digit Symbol-Coding, Block Design  
 and Object Assembly). At NA3 the full battery was

administered as NG was able to perform both the verbal and performance subtests of the battery.

*J. Western Aphasia Battery (WAB; Kertesz, 1982; NA1, NA2, NA3)*

The WAB is an instrument for assessing language function of adults and is able to discern the presence, degree, and type of aphasia. It consists of four oral language subtests – spontaneous speech, auditory comprehension, repetition and naming – that yield five scores based on a rating scale. In addition, tests of reading, writing, arithmetic, gestural praxis, and construction, as well as Raven's Progressive Matrices are included to provide a comprehensive survey of communication abilities and related functions.

*K. Wisconsin Card Sorting Test (WCST; Berg, 1948, Heaton, & PAR Staff, Psychological Assessment Resources Inc., 1993, 2008, NA1, NA3)*

The WCST is used primarily to assess perseveration, abstract thinking and executive functions. As such, it allows assessing strategic planning, organized searching, ability to use feedback to shift cognitive sets, directing behavior toward achieving a goal, and modulating impulsive responding. The participant is presented with a total of 124 cards on the screen (64 in other versions) over a number of trials. In each trial there are four stimulus cards on the screen, where each card displays one of four symbols – triangle, star, cross, or circle – in the colors red, green, yellow, or blue, and in various numbers, ranging from 1 to 4. On each trial a response card is presented at the bottom center under the four stimulus cards. The participant is asked to match the response card to one of the stimulus cards by using a mouse or one of four selectable keys on the keyboard. Each time the participant matches a response card to the stimulus cards, the computer program provides visual (and auditory) feedback about whether the response was correct (“right”) or incorrect (“wrong”). The participant must deduce what the matching rule is, however, the rule shifts after every few trials and the participant has to deduce what the current rule is.

### 3. Results

In this section we will describe changes in NG's functioning as a consequence of his treatment, summarizing results from the perspective of pre-, intermediate/periodic-, and post-treatment assessment:

### 3.1. Language assessment

#### A1. Language production

*Spontaneous speech:* Fluency (in terms of words per minute) was normal in NA1, the grammatical structure of NG's sentences was mildly incorrect and most sentences included correct conjugated verbs and pronouns (Cookie Theft, WAB: Spontaneous speech). A few sentences were missing a verbs (e.g., “..and my children happy..”, see Appendix), and he tended to use plural pronouns instead of the singular when referring to himself (e.g., “and we're having difficulties speaking well”). There were semantic and literal paraphrasias. On many occasions he was aware of his mistakes and tried to correct himself. In NA2 there was some improvement in comparison to the previous evaluation, as reflected by the WAB scores (16/20 in the spontaneous speech subtest compared to 13/20, in NA1), which was due to richer sentences' content. The NA3 assessment produced similar results to NA2 (17/20, see Table 1, Fig. 1).

*Repetition.* Repetition was severely impaired when NG was first assessed (4/100 in WAB Repetition). Yet, in the second evaluation there was marked improvement (35/100). In NA2, there were lexical errors that preserved the meaning (e.g., *happy* instead of *elated*). This error type suggests that the word that NG heard did trigger the semantic network but could not access the correct lexical item. Noticeable improvement was also observed in NA3 (50/100, Table 1, Fig. 1).

*Word retrieval.* In all three assessments there were severe word finding difficulties in spontaneous speech (Cookie Theft). On confrontation naming tasks his performance was severely impaired (NA1: WAB Naming 10/100, BNT – 0). He showed some improvement in the following assessments (NA2: BNT - 2/7; NA3: WAB Naming 37/100, BNT - 1/15), but his performance remained impaired in this area. Phonemic cues (initial sounds, letters and syllables) did not improve his performance at all.

*Articulation and prosody.* These capacities were preserved and were not impacted by the CVA.

#### A2. Comprehension of auditory language

*Phonemic and phonological awareness:* This was tested in NA1 by same/different judgment of auditory consonant-vowel pairs (e.g. “da” vs. “ga”) without lip-reading. NG performed well in this task. In NA2 a more comprehensive assessment of NG phonology was performed using the Phonological Awareness Test (Robertson & Salter, 1997, see Table 2). This

Table 1  
NG's Performance in the Western Aphasia Battery

| Subtest  | Dec 2000/Jan 2001 |              | Feb. 2003   |              | Aug. 2014  |              |

| V.A. Reading comprehension of sentences (max. 40)                |                   | 22           |             | 32           |            | 34           |
| V.B. Reading commands (max. 20)                                  |                   | 5            |             | 6            |            | 8            |
| V.C. Written word stimulus object choice matching (max. 6)       |                   | 5            |             | 6            |            | 6            |
| V.D. Written word stimulus picture choice matching (max. 6)      |                   | 6            |             | 6            |            | 6            |
| V.E. Picture stimulus written word choice matching (max. 6)      |                   | 6            |             | 6            |            | 6            |
| V.F. Spoken words, written word choice matching (max. 4)         |                   | 2            |             | 4            |            | 4            |
| V.G. Letter discrimination (max. 6)                              |                   | 6            |             | n/a          |            | 6            |
| V.H. Spelled word recognition (max. 6)                           |                   | 0            |             | 2            |            | 5            |
| V.L. Spelling (max. 6)   |                   | 0            |             | 0            |            | 3            |
| <b>VI. Writing (max. 100)</b>                                    | <b>28.5</b>       |              | <b>27.5</b> |              | <b>43</b>  |              |
| VI.A. Writing on request (max. 6)                                |                   | 2            |             | 2            |            | 3.5          |
| VI.B. Written output (max. 34)                                   |                   | 0            |             | 0            |            | 0            |
| VI.C. Writing to dictation (max. 10)                             |                   | 0            |             | 0            |            | 0            |
| VI.D. Writing to dictation or visually presented words (max. 10) |                   | n/a          |             | n/a          |            | 5            |
| VI.E. Alphabet and Numbers (max. 22.5)                           |                   | 14           |             | 13           |            | 18           |
| VI.F. Dictated Letters and Numbers (max. 7.5)                    |                   | 2.5          |             | 2.5          |            | 7.5          |
| VI.G. Copying of words of sentence (max. 10)                     |                   | 10           |             | 10           |            | 9            |
| <b>VII. Praxis (max. 10)</b>                                     | <b>9.5</b>        |              |             | n/a          |            | <b>10</b>    |
| VII.A. Drawing (max. 30)   |                   | 19.5         |             | n/a          |            | 29           |
| VII.B. Block design  |                   | n/a          |             | n/a          |            | n/a          |
| VII.C. Calculation (max. 24)                                     |                   | 20           |             | n/a          |            | 22           |
| VII.D. Raven's Colored Progressive Matrices (max. 37)            |                   | 35           |             | n/a          |            | 35           |

632 evaluation revealed that his phonological awareness  
 633 may have also been compromised. Although he  
 634 was able to perform most of the rhyming, isolation  
 635 (e.g., identifying first sound in a word) and deletion  
 636 (e.g., saying a word without one of its parts) tasks,  
 637 he encountered difficulties with tasks that required  
 638 segmentation (e.g., syllables in a word) and blending  
 639 (e.g., integrating separate word sounds into a  
 640 word).

641 *Semantic comprehension:* NG was able to answer  
 642 biographical and general knowledge yes-no questions  
 643 (WAB Yes/no Questions – 54, 57, and 60/60 in NA1,  
 644 NA2, NA3 respectively). He also was competent in  
 645 pointing to real and drawn objects (as well as forms,  
 646 numbers, colors, directions, body parts, etc.), accord-  
 647 ing to a verbal command and did better on this section  
 648 in the later assessments relative to the first (WAB

Auditory word recognition – 49, 56, and 54/60 in  
 NA1, NA2, NA3 respectively).

*Syntactic comprehension:* This function was mod-  
 erately to severely impaired in NG. He had difficulty  
 executing commands that included prepositions.  
 However, he showed marked improvement in this  
 function in each of his two following evaluations  
 (WAB: Sequential commands – 8, 20 and 59 out of  
 80 in NA1, NA2 and NA3 respectively).

### A3. Reading and writing/spelling

*Reading:* This capacity was severely impaired in  
 NG. He could not read aloud words and had great dif-  
 ficulty pronouncing the sounds associated with most  
 written letters. In the DAR (Roswell et al., 2005, see  
 Table 2), conducted in NA2, his word recognition,  
 oral reading, and spelling were at Grade 1 levels.

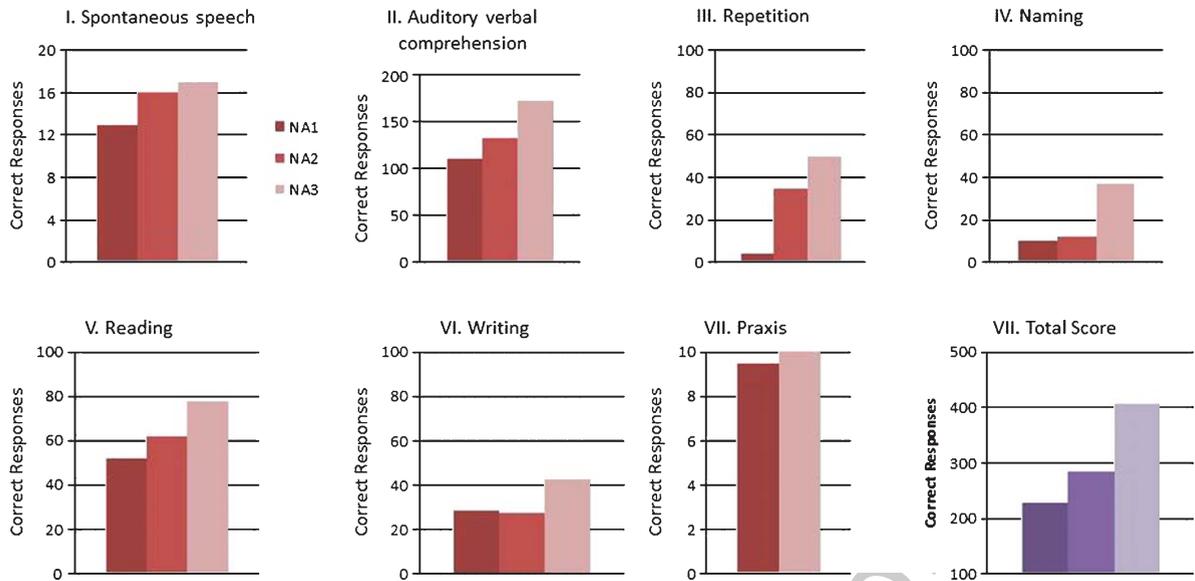

Fig. 1.

It is important to mention that he was able from the beginning of his rehabilitation to derive meaning from written language to a certain extent, and marked improvement was seen throughout the years (WAB: Reading: 52, 62, and 78/100 in NA1, NA2 and NA3, respectively). He was able to point to a written letter according to a verbal command (NA1: WAB: Auditory word recognition – 6/6 items correct). On a test that requires selecting a written word that completes a written sentence he worked slowly, but did better on each evaluation than the previous one (WAB: Reading: Reading comprehension of sentences – 22, 32, 34/40).

Complex reading comprehension is, however, limited. When asked in NA1 to perform written commands he had difficulty doing so, probably because of the language processing difficulties mentioned earlier. Despite some improvement across each evaluation the improvement was only negligible (WAB: Reading: Reading commands - 5, 6, 8/20). He was able to hear a non-word and choose the correct written non-word (e.g., GOB) from a list of written non-words with some accuracy. This suggests that he is capable of some phonological processing and that his reading does not rely completely on the combination of a relatively preserved orthographic route and extensive use of context. Comprehension of written numbers is also relatively preserved. On a simple math test he had no difficulty comprehending written

two-digit numbers (WAB: Calculation – 20/24 (NA1). In the 2014 evaluation, his level had further improved, receiving 22 out of 24 on the same calculation task.

*Writing (letters and numbers):* Writing was also originally severely impaired but improved throughout the years (WAB: Writing: 28.5, 27.5, and 43/100 in NA1, NA2 and NA3, respectively). NG is able to write his own name (WAB: Writing: Writing on request) but cannot write letters to dictation (e.g. WAB: Writing: Writing to dictation – he scored 0 on all three assessments). In his first two assessments, NG could not spell words orally or use cut-out letters to create written words (WAB: Writing: Writing of dictated or visually-presented words – 0 score), but this had improved to 5/10 in his 2014 assessment. Although this does not constitute writing, he could copy a sentence in all evaluations (WAB: Writing: Copying of words in a sentence).

Writing numbers is moderately impaired. He was able to write digits between 1 – 20, displaying his highest score in the third assessment (WAB: Writing: Alphabet and numbers – 14, 13, 18/22.5). He wrote 2-digit numbers to dictation without difficulty but made mistakes on longer numbers (WAB: Writing: Dictated letters and numbers – 2.5/7.5 on both NA1 and NA2. Part of the difficulty was with retaining the numbers in short-term memory. However, he showed marked improvement on this subtest in 2014, receiving a full score.

Table 2

Summary Report of the Phonological Awareness Test (Robertson & Salter, 1997) and the Diagnostic Assessments of Reading (Roswell, Chall, Curtis & Kearns, 2005)

| Phonological Awareness Test |                        |
|-----------------------------|------------------------|
| Rhyming                     | 16/20                  |
| Segmentation                | 9/20                   |
| Isolation                   | 19/25                  |
| Deletion                    | 2/2                    |
| Substitution                | n/a                    |
| Blending                    | n/a                    |
| DAR                         |                        |
|                             | Grade equivalent level |
| Word recognition            | <1-1                   |
| Oral reading                | <1-1                   |
| Reading Comprehension       | <3                     |
| Spelling                    | <1-1                   |
| Vocabulary                  | 11/12                  |

### 3.2. Intellectual functioning

During the initial assessment (NA1) it was impossible to compute an intelligence quotient due to NG's severe language impairments, which rendered him grossly impaired. In fact, scores were produced and calculated solely for 3 subtests, where language involvement was minimal (Block Design, Object Assembly, and Digit Symbol; see Table 3). However, in the final assessment conducted in 2014 (NA3), NG's performance was much improved and he was able to perform most of the sub-tests in the WAIS. His overall intelligence quotient was low average (FSIQ = 81, 10th percentile). He performed much better on the performance tasks (PIQ = 95, 37<sup>th</sup> percentile, average), than on the verbal tasks (VIQ = 73, 4th percentile, borderline), due to his persisting linguistic difficulties. In the RCPM his performance was almost perfect in both NA1 and NA3 (35/36).

### 3.3. Visuo-spatial functions

Object and line drawing identification were preserved in NA1. His performance on construction tasks was within normal limits (WAIS-R: Block design, Scaled score (SS) = 6, Object Assembly, SS = 9). It was, however, lower than expected, based on his pre-morbid level of functioning and profession. On the Block Design subtest he performed slowly and only got a time bonus on one of the items. He constructed all nine items but exceeded the limit on the last three. On the Object Assembly subtest he had difficulty identifying one of the items according to its scattered parts and performed slowly. In the ROCFT Copy subtest he scored 36/36 (>99 percentile). A signifi-

cant improvement was observed in NA3 (WAIS-R: Block design, SS = 10, Object Assembly, SS = 12). In the ROCFT Copy subtest he scored 34/36 (>99 percentile).

### 3.4. Learning/memory processes

NG's ability to acquire novel information and his memory capacities were affected by his CVA. However, it should be noted that it was not possible to gauge accurately his abilities in this domain because of his linguistic difficulties. Thus, the impaired results indicating difficulties in episodic memory should be treated with caution.

*Learning Processes:* In both NA1 and NA3 NG's performance improved throughout trials despite the initial low number of items recalled. Due to the lack of normative data it is impossible to assess the learning curve of the FOME but in the RAVLT his performance was average (43 percentile, Table 4).

*Memory:* His recall performance was impaired both in NA1 and NA3. This is not surprising in light of the verbal assessment measure used in NA3 (RAVLT). Yet, his performance was compromised also in NA1 where naming was not necessary. However, when assessing his performance with a recognition task he achieved full accuracy in both NA1 and NA3. In addition, in contrast to his difficulties in verbal memory his visual memory, assessed with the ROCFT (immediate recall), was intact in both NA1 (28/36, 82–89% percentile) and NA3 (18/36, 41–59 percentile, Table 4).

### 3.5. Executive & Attentional Processes

*Abstract thinking & response set shifting:* NG completed the same number of categories in the WCST in both NA1 and NA3 ( $N=4$ , Table 5). Yet, his performance in NA3 is better compared to NA1 (>16 vs. 11–16 percentiles), since the short version of the WCST (consisting of 64 cards) was administered in the NA3 assessment while the long version (124 cards) in the NA1 assessment. Improvements were also observed in other parameters of the WCST, such as the total errors (from 19 in NA1 to 58 percentiles in NA2), perseverative errors (from 19 to 58 percentiles), non-perseverative errors (from 19 to 58 percentiles) and learning to learn (from 2–5 to >16 percentiles).

*Working memory (WM):* This process could not have been evaluated in its usual verbal sense in NA1. Yet, there was evidence at the time that there

Table 3  
WAIS Subtests and Index/IQ Scores Summary (WAIS-R in 2001, WAIS-III in 2014)

| Subtest                       | 2000/1                    | 2014                      |             |                         |
|-------------------------------|---------------------------|---------------------------|-------------|-------------------------|
|                               | Age-Adjusted Scaled Score | Age-Adjusted Scaled Score |             |                         |
| Picture Completion            |                           | 10                        |             |                         |
| Vocabulary                    |                           | 10                        |             |                         |
| Digit Symbol-Coding           | 5                         | 5                         |             |                         |
| Similarities                  |                           | 3                         |             |                         |
| Block Design                  | 6                         | 10                        |             |                         |
| Arithmetic                    |                           | 3                         |             |                         |
| Matrix Reasoning              |                           | 14                        |             |                         |
| Picture Arrangement           |                           | 8                         |             |                         |
| Comprehension                 |                           | 6                         |             |                         |
| Symbol Search                 |                           | 3                         |             |                         |
| Object Assembly               | 9                         | 12                        |             |                         |
| 2014                          |                           | IQ/Index Scores           | Percentiles | 95% CI                  |
| FSIQ                          |                           | 81                        | 10          | 77–85                   |
| PIQ                           |                           | 95                        | 37          | 89–102                  |
| VIQ                           |                           | 73                        | 4           | 69–79                   |
| Verbal Comprehension Index    |                           | 82                        | 12          | 77–88                   |
| Perceptual Organization Index |                           | 107                       | 68          | 99–114                  |
| Working Memory Index          |                           | 57                        | 0.2         | 53–66                   |
| Processing Speed Index        |                           | 69                        | 2           | 64–82                   |
|                               |                           |                           |             | Qualitative Description |
|                               |                           |                           |             | Low average             |
|                               |                           |                           |             | Average                 |
|                               |                           |                           |             | Low                     |
|                               |                           |                           |             | Low average             |
|                               |                           |                           |             | Average                 |
|                               |                           |                           |             | Very low                |
|                               |                           |                           |             | Low                     |

| Recognition      | 3/3         |             | 15/15     | 96          |

Note. \*Based on Ganguli et al. (2010) norms of sum of three learning trials.

Table 5  
NG performance in the WCST

| WCST Scores                     | Raw Scores 2000/1 | %iles | Raw Scores 2014 | %iles |
|---------------------------------|-------------------|-------|-----------------|-------|
| Trials Administered             | 102*              |       | 64              |       |
| Total Correct                   | 72                |       | 51              |       |
| Total Errors (%)                | 30                | 19    | 13              | 58    |
| Perseverative Responses (%)     | 11                | 42    | 6               | 86    |
| Perseverative Errors            | 11                | 37    | 6               | 79    |
| Nonperseverative Errors (%)     | 19                | 8     | 7               | 42    |
| Conceptual Level Responses (%)  | 66                | 25    | 48              | 63    |
| Categories Completed            | 4                 | 11–16 | 4               | >16   |
| Trials to Complete 1st Category | 11                | >16   | 14              | >16   |
| Failure to Maintain Set         | 2                 | >16   | 1               | >16   |
| Learning to Learn               | -14.92            | 2–5   | 4.40            | >16   |

\*The test was terminated because of fatigue and loss of concentration.

803 are difficulties in this area in its broader sense.  
 804 For example, in the WCST there were difficulties  
 805 maintaining set (% Conceptual level responses – 25  
 806 percentile). In addition, on the FOME there was some  
 807 difficulty keeping track of objects he had already

recalled within the same trial (judging by the repeti-  
 tion errors). This may be connected to oscillations  
 in concentration and to difficulty using short-term  
 phonological memory as a buffer that stores infor-  
 mation in a phonological code, thus enabling the

808  
 809  
 810  
 811  
 812

813 simultaneous manipulation of information (e.g. on  
814 the WCST: storing the name of the sorting strategy  
815 while analyzing the current sorting problem). In  
816 NA3 some improvement was observed in working  
817 memory: NG indices in the WCST showed that he  
818 was more able to maintain set (% Conceptual level  
819 responses – 68 percentile). Yet, his WM index in the  
820 WAIS-III was still very low (<1 percentile).

#### 821 4. Discussion

822 The present study presents a long-term therapy  
823 and follow-up, extending approximately fifteen  
824 years, of NG, who suffered a left hemorrhagic cerebrovascular  
825 accident (CVA) at the age of 53. As a result of his CVA,  
826 significant language comprehension and production impairments,  
827 in addition to alexia and agraphia, were observed. He was first  
828 treated at the hospital's rehabilitative unit. He later received  
829 intensive rehabilitative treatment at the Center for Cognitive  
830 Rehabilitation of the Brain Injured at the Feuerstein Institute  
831 (FI) for several years (2001–2010).  
832  
833

834 As reflected on the range of tests administered,  
835 NG has made huge progress in his therapy. He has advanced  
836 greatly in his language capacities. His conversation skills have  
837 significantly improved and he has made much progress in his  
838 ability to repeat words. He has improved his word-finding  
839 abilities (less paragrammatism and circumlocutions) and he  
840 can successfully discuss different topics using substantive  
841 vocabulary to get to his point. He has shown marked  
842 improvement in his reading and writing. He can now associate  
843 letters with their sounds in order to orally read a written  
844 word, read aloud simple sentences and write simple words  
845 from visual representation. In addition, NG can write new  
846 words from dictation via phoneme–grapheme conversion.  
847 This amelioration is expressed in the rise of both the  
848 aphasia quotient and cortical quotient in the WAB (39.9,  
849 54.7 and 68.9 aphasia quotient and 42.6, 43.0 and 65.3  
850 cortical quotient in NA1, NA2, NA3).  
851  
852  
853

854 NG's short-term memory recall remains impaired  
855 but his recognition and visual memory capabilities are intact.  
856 NG also shows high levels of abstract thinking. NG's overall  
857 improvement is most obvious when comparing his scores in  
858 general intelligence (WAIS). In the first assessment,  
859 approximately 7 months after his CVA, NG was only able  
860 to complete 3 non-verbal subtests. However, in the final  
861 assessment in 2014,

862 not only did his scores on these 3 subtests increase,  
863 but he was able to perform most of the sub-tests.

864 NG still suffers from word finding difficulties and  
865 finds confrontation naming tasks a challenge; however,  
866 he is cognizant of these difficulties and tries hard to  
867 correct himself. There still remains some semantic and  
868 literal paraphasias in his spontaneous speech and he  
869 displays difficulties in self-monitoring of grammatical  
870 errors and understanding of complex speech. When  
871 conversing with others, the speaker's pace of speech  
872 has to be slower than normal to allow NG more  
873 processing time and his short term memory is still  
874 impaired.

875 NG has also succeeded in recovering his functionality  
876 and adaptability. He has returned to work in his  
877 architectural firm, and he functions on a high level on  
878 a day to day basis. He is generally independent, does  
879 not need accompaniment, drives by himself, makes  
880 telephone calls, corresponds with clients and continues  
881 to work on prestigious projects.

882 Research has revealed that therapy for chronic  
883 aphasia is more effective if sufficiently prolonged or  
884 intensive (Basso & Macis, 2011). This is a crucial  
885 aspect of the application of MLE oriented treatment,  
886 particularly as it involved the application of FIE. In  
887 one review, Bhogal, Teasell & Speechley (2003) found  
888 that significant treatment effects resulted when  
889 intensive (at least 8.8 hours per week) training was  
890 provided for a total of approximately 100 hours. This  
891 was certainly the case for the treatment of NG's  
892 chronic aphasia as he received intensive weekly  
893 therapy extending almost 15 years.

894 Speech therapy is the most effective form of  
895 rehabilitation for most aphasic patients (Barisa, Noggle,  
896 Salisbury & Boseck, 2015). Most patients receive  
897 conventional speech therapy targeting the particular  
898 areas of difficulty. The development and application  
899 of NG's individual speech therapy focused on his  
900 specific deficits. Efforts were made to improve his  
901 word finding difficulties, repetition and conversational  
902 skills and to link them to cognitive strategies such as  
903 finding the main ideas in the language, widening his  
904 mental field, gathering relevant information in a  
905 systematic manner, and the like. As noted above,  
906 this individual-focused therapy had a tremendous  
907 effect on his language skills. Positive effects of this  
908 type of treatment have also been documented in the  
909 literature (e.g. Brady et al., 2012).

910 Another method of treatment for chronic aphasia  
911 is tele-therapy. This is the use of telecommunications  
912 technologies to connect a clinician with remote  
913 clients, or use of web-based or app-based exercises

914 for independent work, which clients can access when-  
 915 ever they like (Steele et al., 2014). NG uses phone  
 916 applications to assist him with his language diffi-  
 917 culties and to improve his functioning (e.g., an app  
 918 called “Speak It” helps him read). Technology, such  
 919 as text to audio software, was also used in therapy  
 920 to aid him with conversation skills, and in his pro-  
 921 fessional life. In the early stages of the use of these  
 922 applications, he was mediated to plan their use, con-  
 923 nect them to goals and desired outcomes, and review  
 924 his decisions regarding when and how to use them.  
 925 In a recent review on aphasia tele-rehabilitation, it  
 926 was concluded that tele-practice has demonstrated  
 927 its viability as a method of service delivery to apha-  
 928 sic patients (Hall et al., 2013). A study by Steele  
 929 et al., (2014) found marked improvement in subjects’  
 930 functional communication and feelings of confidence  
 931 following treatment combining tele-therapy and on-  
 932 line language exercises. This was clearly evident in  
 933 NG’s use of them.

934 In addition, functional communication is maxi-  
 935 mized when therapy for aphasia involves the patient  
 936 and the family/caregiver (Brady et al., 2012). NG’s  
 937 wife was highly involved in his therapeutic process;  
 938 she accompanied her husband to sessions for the first  
 939 year of treatment, assisted him with exercises per-  
 940 formed at home, and provided him with emotional  
 941 support throughout the whole process. Therapy that  
 942 acknowledges the role of the caregiver of the patient  
 943 generally has a positive impact on quality of life and  
 944 communication (Sorin-Peters, 2004).

945 The structure and format of therapy that NG  
 946 received at the FI, namely, the Mediated Learning  
 947 Experience and the Feuerstein Instrumental Enrich-  
 948 ment Program, acted as catalysts in his rehabilitation.  
 949 This style of therapy improved NG’s functioning by  
 950 making use of his strengths and working on the areas  
 951 that were damaged. Use of state of the art equipment  
 952 and reference to mathematical skills specific to his  
 953 field made NG feel that he was able to perform, and  
 954 helped him rebuild his confidence. Tasks that proved  
 955 too difficult to him were bypassed by using strategies  
 956 to intellectually stimulate him in other ways. He was  
 957 then able to transfer what he learned to other areas  
 958 of functioning. His wife reported that the hope that  
 959 NG was given alongside the effectiveness of the MLE  
 960 method helped her husband bridge the gap between  
 961 where he was and where he wanted to be. This created  
 962 optimism in NG which ultimately led to his marked  
 963 improvement in language. The contribution of intens-  
 964 ity and prolonged therapy using IE and the MLE was  
 therefore central to NG’s improvement.

## Conflict of interest

1107 **Appendix**1108 *January 2001*

1109 Ok, well there's I think two men and one girl a  
 1110 younger kid and there are several problems there's  
 1111 one of them is all kinds of water that's spilling all over  
 1112 the place the older woman is spilling water onto the  
 1113 floor and onto the dinner... area. Were the rest of it is  
 1114 basically normal and there's another issue... where  
 1115 the two girls are about to fall and the older I guess  
 1116 the girl, the husband the boy is trying to get girling  
 1117 getting food but they're falling and hurt them self's  
 1118 this thing what's it called (\*stool) this is in the process  
 1119 of being falling when she's holding here food...

1120 *February 2003*

1121 Ok, there's several unusual differences which in  
 this area that we're talking about... so the woman

woman right? is water is spriding... not sprid- 1122  
 ing... on the floor. Um there's 2 kids the guy is about 1123  
 to fall um... Although he was design so that girl was 1124  
 to get what's it called I don't know what with it before 1125  
 she's about to fall and... .alright. I guess that's it. 1126

24.06.2014 1127

This guy is falling because he is trying to get some 1128  
 food from... you know what it is... it's a sweet food. 1129  
 This is the daughter, or the sister or something like 1130  
 that. This guy is falling. The mother is noticing that 1131  
 water is shpritzing all over the house and she didn't 1132  
 see it... and she's cleaning... glass... and it's pretty 1133  
 ridiculous that they're doing that... and she's also 1134  
 going to fall soon. It looks like the glass (window 1135  
 pane) is not here. 1136
